

Autism

According to the Autism Society of America, autism is a developmental disability that typically appears during the first three years of life. The result of a neurological disorder that affects functioning of the brain, autism and its associated behaviors occurs in approximately 1 of every 150 individuals. Autism interferes with the normal development of the brain in the areas of reasoning, social interaction and communication skills. Children and adults with autism typically have difficulties in verbal and non-verbal communication, social interactions and leisure or play activities. Its prevalence rate now places it as the third most common developmental disability, yet many people of the public, including many professionals in the medical, educational, and vocational fields are still unaware of how autism affects people and how to effectively work with individuals with autism.

These developmental syndromes are widely misunderstood and can be difficult to treat successfully. The latest scientific studies show that autistic disorder spectrum symptoms appear to be related to problems with internal communication among different brain areas. ABF treatment methods can result in noted improvement in symptoms of autism and "Asperger's disorder" - high functioning autism. Regardless of the difficulty on treating these conditions, ABF has made successful reductions in the symptoms of autism or "Asperger's disorder."
